## 32 **Abbreviations**

33 AIR: **alcohol insoluble residues**; AX: Arabinoxylan; XYN2:  $\beta$ -1,4 endo-xylanase;  
34 FA: Ferulic acid; FAEA: ferulic acid esterase; HCAs: Hydroxycinnamic acids;  
35 HPAEC: Anion exchange chromatography; HPLC: High performance liquid  
36 chromatography; IVDMD: *in vitro* dry matter digestibility; LmSee1: *Lolium*  
37 *multiflorum* senescence promoter; PAHBAH: *p*-hydroxybenzoic acid hydrazide;  
38 *p*CA: *p*-coumaric acid; TFA: trifluoroacetic acid.

## 40 **Abstract**

41 Tall fescue plants (*Festuca arundinacea*) constitutively expressing vacuole or  
42 apoplast targeted ferulic acid esterase from *Aspergillus niger* were retransformed  
43 with a senescence induced and apoplast targeted  $\beta$ -1,4 endo-xylanase from  
44 *Trichoderma reesei*. Enzyme activities in co-expressing plants stabilized after  
45 repeated vegetative propagation, with xylanase activity in senescent leaves  
46 increasing and ferulic acid esterase activity decreasing after tillering. Plants co-  
47 expressing both enzymes in the apoplast, with the lowest levels of ferulate  
48 monomers and dimers and the lowest levels of cell wall arabinoxylans, released  
49 ten times more cell wall hydroxycinnamic acids and five times more arabinoxylan  
50 from the cell wall on autodigestion compared to expression of ferulic acid esterase  
51 or xylanase alone. These plants also showed a 31% increase in **cellulase-**  
52 mediated release of reducing sugars, a 5% point increase in in-vitro-dry-matter-  
53 digestibility and a 23% increase in acetyl bromide soluble lignin. However, plant  
54 growth was adversely affected by expressing FAE in the apoplast, giving plants  
55 with narrower shorted leaves, and **a 71% decrease in biomass.**

58

**Introduction**

The potential of grass lignocellulose for the production of fermentable sugars to ethanol arises from their high yield, low cost, high sustainability on marginal land and low impact on food supply and the environment compared to current grain-based ethanol (Rogner 2000). However, due to the complex structure of grass cell walls and their recalcitrance to enzymatic attack, the conversion of lignocellulosic biomass to ethanol is still an inefficient process (Saha 2003), requiring expensive pre-treatments, high enzyme inputs, and long digestion times (Mosier et al. 2005).

In relation to the structure of plant cell walls, some hemicelluloses, in contrast to cellulose, are branched xylan-rich polysaccharides and as such require a spectrum of hydrolytic enzymes for hydrolysis (Biely 1985). In grasses, arabinose constitutes the main side chain connected to the xylan backbone which is further esterified by phenolic acids where ferulic acid is the most common. The importance of ferulic acid stems from its ability to undergo oxidative coupling reactions to form ferulate dimers cross-linking xylan (Hatfield et al. 1999) and in linking lignin to the xylan/cellulose network via a lignin-ferulate-xylan complex (Buanafina 2009).

Xylanases (i.e.  $\beta$ -1,4 endo-xylanase), are the major enzymes required for arabinoxylan (AX) breakdown as reviewed by Collins *et al.*, (2005) but a second important class of enzymes, which plays a key role in the degradation of the complex AX cell wall structure, are the hydroxycinnamoyl hydrolases such as ferulic acid esterases (FAE) (Faulds and Williamson 1993) . These enzymes have

81 the ability to hydrolyse the esterified feruloylated groups involved in cross-linking  
82 between AX and between AX and lignin (Williamson et al. 1998) and have been  
83 classified according to their substrate specificity and amino acid sequence into 4  
84 types A, B, C and D (Crepin et al. 2004).

85 Ferulic acid esterase A from *Aspergillus niger* is one of the most widely studied of  
86 the feruloyl esterases and is known to act on ferulic acid residues attached to the  
87 O-5 of arabinose in arabinoxylan (Ralet et al. 1994). FAEA releases 5-5' and 8-0-  
88 4' ferulate dimers from plant cell walls when incubated with xylanase or when pre-  
89 treated with xylanase (Kroon et al. 1999). This positive synergism of FAEA with  
90 other catalytic or non-catalytic proteins is shown by the release of ferulates from  
91 different substrates by different ferulic acid esterases alone or in combinations  
92 with xylanases. For example, the efficiency of ferulate release by *A. niger* FAEA  
93 from wheat straw increases when combined with xylanase or with *T. reesei*  
94 cellulase during saccharification (Tabka et al. 2006), or when fused to the non-  
95 catalytic *T. reesei* swollenin protein (Levasseur et al. 2006). Generally, the  
96 glycoside hydrolase family 11 xylanases favours the release of ferulic acid while  
97 family 10 xylanases are more efficient at releasing ferulate dimers (Faulds et al.  
98 2003).

99 Strategies for producing the large amounts of exogenous cell wall degrading  
100 enzymes required to degrade lignocellulosic biomass into its constituent sugars  
101 include the production of transgenic plants with high levels of enzyme activity. To  
102 this end, the production of an active insoluble aggregate of xylanase in tobacco  
103 where a Zera-xylanase chimeric protein accumulated within ER-derived protein  
104 bodies has been demonstrated (Llop-Tous et al. 2011), as well as the targeting of  
105 constitutive expression of the *xyn2* gene from *Trichoderma reesei* or the alkali-

106 thermostable xylanase gene from *Bacillus* sp. to the chloroplast or peroxisome  
107 (Leelavathi et al. 2003; Bae et al. 2006; Verma et al. 2010). In addition, an  
108 elegant new way of expressing xylanase in plants without inducing problems with  
109 plant development has recently been demonstrated by engineering thermo-  
110 regulated intein splicing to control induced xylanase catalytic activity (Shen et al.  
111 2012).

112 An alternative approach to reducing the requirements for large amounts of cell wall  
113 degrading enzyme may be the use of genetically improved biomass with modified  
114 cell wall structures produced by induced targeting of *in-planta* expression of these  
115 enzymes. There have been only a few reports of the effects of *in-planta*  
116 expression of ferulic acid esterase. When FAEA, under the control of an  
117 endosperm-specific promoter was expressed in wheat, the water-unextractable  
118 arabinoxylan of grain cell walls increased by 15%–40% and monomeric ferulic  
119 acid decreased by 13%-34% irrespective of the addition of a 3' KDEL, but seeds  
120 were shrivelled with a 20–50% decrease in weight (Harholt et al. 2010). However,  
121 transgenic plants of *Arabidopsis thaliana* expressing *Aspergillus nidulans* feruloyl  
122 esterase in the apoplast showed no visible phenotype and the induced  
123 compositional changes increased biomass degradability (Pogorelko et al. 2011) .  
124 A type B ferulic acid esterase (*faeB*) from *Aspergillus niger* when expressed in  
125 alfalfa targeted to the apoplast, endoplasmic reticulum or vacuole, modified cell  
126 wall composition with a reduction in ester linkages but with elevated lignin,  
127 resulting in recalcitrance to digestion by mixed ruminal microorganisms but with no  
128 visible plant phenotype (Badhan et al. (2014). [However grass cell wall architecture](#)  
129 [is much more dependent upon the incorporation of ferulates than in alfalfa, which](#)  
130 [contain relatively low levels of ferulate.](#)

131 When constitutively expressed in leaves of *Lolium multiflorum* (Buanafina et al.  
132 2006) or *Festuca arundinacea* (Buanafina et al. 2008), *Aspergillus niger* ferulic  
133 acid esterase (*faeA*) targeted to the vacuole had little effect on plant growth or  
134 biomass yield but resulted in reduced levels of cell wall esterified monomeric and  
135 dimeric ferulates and increased rates of *in vitro* dry-matter digestibility.  
136 Constitutive intracellular targeted expression of FAEA to the apoplast,  
137 endoplasmic reticulum or Golgi in *Festuca* also disrupted feruloylation of the  
138 growing cell wall with significant reductions in the levels of monomeric and dimeric  
139 ferulates resulting in increased biodegradability in terms of cell wall digestibility  
140 and increased rates of cellulase-mediated release of fermentable sugars  
141 (Buanafina et al. 2010). In addition, the release of monomeric and dimeric ferulic  
142 acids from cell walls on autodigestion of leaves expressing FAEA was enhanced  
143 several fold by the addition of exogenous  $\beta$ -1,4 endoxylanase (Buanafina et al.  
144 2008; 2010). Expression of beta endo-xylanases in plants has however received  
145 considerable attention, although reports of the effects on plant growth and  
146 development of constitutive expression of either microbial or fungal endo-  
147 xylanases in different cellular compartments in both monocot or dicot species are  
148 highly inconsistent (reviewed by Taylor et al. 2008; Bae et al. 2008; and Sainz  
149 2009). Few reports however have described the effects of these *in-planta*  
150 expressed cell wall degrading enzymes on cell wall structure. Expression of  
151 *Trichoderma reesii xyn2* controlled by a senescence promoter in the apoplast of  
152 *Festuca arundinacea*, had no effect on the level of monomeric hydroxycinnamic  
153 acids or lignin in the cell walls, but resulted in increased levels of ferulate dimers,  
154 decreased levels of xylose and increased levels of arabinose in the cell walls,  
155 compared with non transformed plants (Buanafina et al. 2012). High-level

156 xylanase expression in the apoplast of *Festuca arundinacea* leaves also resulted  
157 in ethylene and H<sub>2</sub>O<sub>2</sub> accumulation and necrotic lesions on the leaves indicative of  
158 plant defence responses analogous to foliar pathogen attack (Buanafina et al.  
159 2012). These changes in cell wall composition resulted in decreases in both tissue  
160 digestibility and cellulase mediated sugar release (Buanafina et al. 2012).

161 In order to test if *in-planta* co-expression of FAEA and XYN2 could improve the  
162 digestion of polysaccharides and increase post harvest cell wall deconstruction in  
163 grasses more effectively than expression of xylanase or FAE alone, FAEA  
164 expressing plants were re-transformed with XYN2. To date *in-planta* co-  
165 expression of these two cell wall degrading enzymes has not been previously  
166 tested and our experience of expressing FAE and xylanase in *Festuca* indicated  
167 that constitutive co-expression might be detrimental to cell growth. We specifically  
168 chose therefore to separate the activities of the two enzymes either spatially or  
169 temporally using the *Lolium* See1 senescence enhanced promoter for xylanase  
170 expression as this is activated at the end of plant growth prior to the start of leaf  
171 senescence (Li et al. 2004). Our aim was to determine the feasibility of exploiting  
172 synergy between FAE and xylanase to achieve higher levels of cell wall  
173 arabinoxylan deferuloylation both at the end of active leaf growth during  
174 senescence, and subsequently following cell death. The effects of constitutive co-  
175 expression of FAEA in the vacuole or apoplast combined with senescence  
176 inducible expression of XYN2 in the apoplast, on plant growth, cell wall ferulates  
177 and cell wall sugar composition, lignification, and cell wall degradability are  
178 reported here.

179

## 180 **Materials and Methods**

181 **Plasmid construction**

182 The plasmids used in this study (Figure 1a), were based on expression vectors  
183 containing the *faeA* and *xyn2* genes that have been described previously  
184 (Buanafina et al. 2008, 2010, 2012). The *Trichoderma reesei*  $\beta$ -1,4 endo-xylanase  
185 gene (*xyn2*) gene was placed under the control of a *Lolium multiflorum*  
186 senescence promoter (LmSee1) targeted to the apoplast (pIOM6). The *faeA* gene  
187 was placed under the rice actin promoter and targeted to the apoplast (pIGB6). In  
188 addition, a new construct with constitutive FAE targeted to the vacuole (pINH1 $\Delta$ )  
189 was made by modifying the original pTP3 vector where the Knp1-ECORI fragment  
190 (Del in Figure 1a) was removed from the actin promoter in order test if this  
191 modification would increase FAEA activity.

193 **Plant transformation**

194 In order to test re-transformation strategies new transformants were produced by  
195 retransformation of plants previously transformed with pINH1 $\Delta$  or with pIGB6  
196 [plant T27 (Buanafina et al. 2008)] (Figure 1a), with a xylanase containing vector  
197 pIOM6 (Buanafina et al. 2012). Several plants expressing each FAE construct  
198 were selected and the shoot tips cultured *in vitro* to produce *in vitro* stock plants.  
199 Callus and then cell suspensions were produced (as in Buanafina et al. 2006) and  
200 cell suspensions cultures were re-transformed by bombardment with plasmid  
201 pIOM6, containing the XYN2 gene, and as the FAE expressing plants were  
202 hygromycin resistant, they were co-transformed with pBKS containing the *npII*  
203 gene under the maize ubiquitin promoter and transformants selected with  
204 paromomycin (50-100 mg L<sup>-1</sup>).

205 ***Plant growth and harvesting***

206 Regenerated plants were transferred to soil in 8" pots containing a 5:1 mixture of  
207 Miracle-Gro Potting Mix (The Scotts Company, Marysville, OH 43041) and  
208 vermiculite, and grown in a controlled environment chamber at 22/16°C (day/night)  
209 temperature, 16 h photoperiod, and 180  $\mu\text{mol photons m}^{-2} \text{s}^{-1}$  photosynthetically  
210 active radiation. When established, plants were screened for FAE activity. As  
211 plants reached maturity they were screened for xylanase activity using green or  
212 naturally senescent leaves. Plants showing the highest xylanase activities were  
213 harvested to 5 cm above soil level and the plants allowed to regrow. Sub samples  
214 of harvested leaves from regrown plants were frozen for FAE and xylanase activity  
215 and for Southern and self-digestion analysis. The remaining tissue was freeze-  
216 dried and powdered for cell wall chemistry, digestibility and lignin determinations.

217  
218 ***Southern analysis of transgenic plants***

219 Total genomic DNA for Southern analysis was isolated from leaves frozen in liquid  
220 nitrogen. Each DNA sample was digested overnight at 37°C with HindIII restriction  
221 enzyme (Roche) to liberate the *fae2* gene. For the *xyn2* gene samples were  
222 digested with EcoRI and NotI. Ten micrograms of digested genomic DNA were  
223 separated by agarose electrophoresis, transferred onto Hybond N<sup>+</sup> membrane by  
224 capillary blotting according to the manufacturer's instructions (Roche) and DNA  
225 was fixed to the membrane by UV cross-linking and probed using a digoxigenin-  
226 labelled *fae2* or *xyn2* probe, prepared by PCR of plasmid DNA as described in  
227 Buanafina *et al.* (2010, 2012).

228 **Determination of XYN2 and FAEA activities**

229 For enzyme activities, fresh leaves were ground to a fine powder in liquid nitrogen  
230 and total protein was extracted with 0.1 M Na acetate, pH 5.5 buffer. FAEA  
231 activities were determined in soluble protein extracts incubated with 24 mM ethyl  
232 ferulate as substrate, at 28°C for 24hrs, and the released ferulic acid was  
233 determined by high-performance liquid chromatography (HPLC) as described in  
234 Buanafina *et al.* (2012).

235 One unit of FAE activity equals 1 µg ferulic acid released from ethyl ferulate in 24  
236 h at 28°C. Xylanase activities were determined by mixing crude protein extracts  
237 (190 µl) and 120 µl of 2% Oat Azo-xylan (Megazyme) as substrate. As a control  
238 known amounts of IRG 40 xylanase (Genencor Inc) were also incubated with  
239 buffer and Azo-xylan. After incubation for 23h at 37 °C, the reaction was stopped  
240 with 800 µl of 98% ethanol (v/v) and the water-soluble blue products released from  
241 Azo-xylan measured at 590 nm by spectrophotometry as in Buanafina *et al.*  
242 (2012). Xylanase IRG 40 from *T. reesei* (Genencor Inc) of known specific activity  
243 determined with Birchwood xylan substrate using the 3,5,dinitrosalicylic acid  
244 method was used as a standard. One unit of plant derived xylanase activity was  
245 equivalent to 1 unit of IRG 40 xylanase, defined as 1 µmole xylose released from  
246 Azoxylan min<sup>-1</sup> at 37°C.

247

248 **Preparation of isolated cell walls**

249 Cell walls were prepared as follows: 150 mg of freeze-dried milled samples were  
250 boiled in 90% ethanol, centrifuged and the supernatant removed. Pellets were  
251 incubated in 90% ethanol, with shaking at room temperature for 10 min,  
252 centrifuged to remove the supernatant and the procedure repeated. Pellets were

253 then washed with 100 % methanol, shaken for 10 min, centrifuged and the  
254 supernatant discarded. The procedure was repeated with distilled water and  
255 shaken for 1 h, centrifuged and the pellets of purified cell walls (AIR) freeze dried.

256

257 ***Determination of cell wall hydroxycinnamic acid and arabinoxylan***  
258 ***composition***

259 Quantitative analysis of ester-bound HCAs was determined in isolated cell walls  
260 by High Performance Liquid Chromatography (HPLC) carried out as previously  
261 described (Buanafina et al. 2012). The levels of the monosaccharides xylose, and  
262 arabinose in isolated cell walls were determined by High Performance Anion  
263 Exchange Chromatography (HPAEC) of hydrolysed samples based on the method  
264 of Øbro et al. (2004) with modifications as described in Buanafina et al.(2012) .

265

266 ***Lignin Determinations***

267 ***Acetyl bromide soluble lignin:*** Cell wall material for analysis was  
268 prepared according to Dean (1977). Approximately 50 mg of freeze-dried ground  
269 tissue was sequentially washed with ethanol (95%) / toluene for 4 h, followed by  
270 95% ethanol for 4 h and then water for 2 h. Following washes, pellets were  
271 lyophilized overnight and lignin content of dried material determined using the  
272 acetyl bromide method (Chang et al. 2008). Briefly, 5 mg of cell wall tissue was  
273 digested in 1 ml 25 % acetyl bromide in acetic acid and incubated in a 70°C water  
274 bath for 30 min and vortexed every 10 min. Following digestion and cooling; 5 ml  
275 acetic acid was added to each sample. To 300 µl of the mixture, 400 µl of 1.5 M  
276 NaOH and 300 µl of 0.5 M hydroxylamine hydrochloride were added. The solution  
277 was mixed, diluted with 1.5 ml acetic acid and the absorbance of the solution read

278 at 280 nm using a Multiskan Spectrum high performance spectrophotometer  
279 (Thermo Scientific). A blank was used to correct the background absorbance of  
280 the reagents. Lignin concentrations were calculated using the extinction coefficient  
281 (17.75 cm<sup>2</sup>/g) derived from purified HCL-dioxane lignin isolated from corn stems  
282 (Fukushima and Hatfield 2004).

283 **Klason Lignin:** Determinations were based on the Tappi T 222 OM-11  
284 method (2011) using 0.5 g of freeze dried powdered sample, hydrolysed with 5 ml  
285 of 72 % H<sub>2</sub>SO<sub>4</sub> for 2 h at ~ 20 °C, with stirring every 15 minutes. Deionised water  
286 (140 ml) was added and samples refluxed for 4 h. Filtered sample were washed  
287 with deionised water, dried and weighed and then ashed and reweighed. Based  
288 on in-house QC material for Klason lignin RSD = 0.03487.

289

### 290 **Digestibility Determinations**

291 **Auto-digestion:** The loss of cell wall HCAs and sugars mediated by the  
292 action in *in-planta* expressed FAEA and XYN2 was calculated as the difference  
293 between amounts in purified cell wall AIR and the amounts found in AIR recovered  
294 from digested cell wall pellets. Briefly, leaves (1.0 g fresh wt) were first ground in  
295 liquid nitrogen and then incubated in 2 ml 0.1 M Na acetate extraction buffer pH  
296 5.5 at 37 °C for 48 h. Following centrifugation, cell walls were extracted from the  
297 self-digested pellets (as described above) and incubated with either 1M NaOH for  
298 24h at 25 °C under nitrogen and the released ferulates quantified by HPLC, or  
299 were hydrolysed with TFA and the levels of xylose and arabinose quantified as  
300 described above.

301 **Cellulase mediated sugar release from autodigested cell walls:** Freeze-  
302 dried powdered leaf material (10 ± 0.2 mg), was incubated with shaking in

303 extraction buffer (0.1 M sodium acetate, pH 5.5), for 12 h, and the supernatant  
304 containing soluble sugars removed following centrifugation. Washed, autodigested  
305 cell wall pellets were incubated with 63 units/ml of *T. reesei* cellulase (Sigma) at  
306 37 °C for 24 h. Reducing sugars in the medium were determined by the p-  
307 hydroxybenzoic acid hydrazide (PAHBAH) method as in Buanafina et al. (2010).  
308 All assays were performed in duplicate.

309 ***In vitro dry matter digestibility (IVDMD):*** The digestibility of leaves was  
310 estimated by a two-stage *in vitro* pepsin-cellulase solubility technique (Jones and  
311 Howard, 1975), which determines the amount of biomass remaining at the end  
312 point of 48h digestion of 1.0g dry weight of powdered whole tissue. Based on in-  
313 house reference samples included in each analysis, the RSD of the method was  
314 0.1904.

### 315 ***Statistical analysis***

316 All statistical analyses were performed with Statistical Analysis System (SAS)  
317 (2010)-software. Values in the text are means  $\pm$  standard error (sem). Bars with  
318 different letters are significantly different (Tukey's,  $\alpha = 0.05$ ). Linear correlations  
319 between HCAs and soluble acetyl bromide lignin were calculated using the  
320 Pearson product-moment correlation coefficient. Before ANOVA some of the data  
321 was log transformed to stabilize variance and a permutation test was applied using  
322 GenStat for Windows 16th Edition, VSN International Ltd., Hemel Hempstead, UK.

323

## 324 **Results**

### 325 ***Transformation and molecular analysis of plants co-expressing FAEA and*** 326 ***xylanase***

327 Previously produced plants expressing FAEA targeted to either the vacuole (line  
328 397) (Buanafina et al. 2008) or apoplast (line 320) (Buanafina et al. 2010) were re-  
329 transformed with apoplast targeted XYN2 regulated by a senescence promoter in  
330 the combinations shown in Figure 1a&b. Three T0 plants from each of the 320 and  
331 397 lines were selected at random without reference to their expressed enzyme  
332 activities for genomic DNA extraction and Southern hybridization analysis using  
333 *xyn2* and *faeA* genes as probes in order to confirm integration of the transgenes.  
334 Following DNA extraction samples were digested with HindIII, (releasing a 1.2-Kb  
335 fragment containing the *faeA* sequence) or with EcoR1/NotI, (releasing a 0.595 Kb  
336 fragment containing the *xyn2* sequence). The hybridization patterns observed  
337 were absent in controls, and confirm the integration of the *faeA* and *xyn2* genes in  
338 the plant genome (Figure 1c).

### 340 ***FAEA and xylanase activities of leaf extracts of senescing T0 and T5 plants.***

341 Five 320line plants produced by re-transforming a single parent plant constitutively  
342 expressing apoplast targeted FAEA (plant T27 [Buanafina et al. 2008]), (Figure 2  
343 a&c), and 15 plants of the 397line produced by re-transforming three  
344 independently transformed parent plants constitutively expressing vacuole  
345 targeted FAEA, (Figure 2b&d), showed FAEA and XYN2 activities similar to those  
346 reported previously in *Festuca* (Buanafina et al. 2006, 2008, 2012).

347 Three plants from line 320 and four plants from line 397 were selected for further  
348 analysis. Based on previous results where the levels of XYN2 expression in

349 *Festuca* plants transformed with XYN2, increased following cycles of vegetative  
350 propagation (Buanafina et al. 2012) , plants expressing FAEA and XYN2 were  
351 propagated by *in vivo* tillering and re-growth for five cycles to give T5 generation  
352 plants before further analysis. As previously found, the levels of XYN2 activity  
353 were significantly higher in T5 generation plants compared to activities in T0  
354 plants, in most of the selected lines (Figures 2e&f), with an average 24 fold  
355 increase in xylanase activity in T5 plants of the 320 line and an average 6 fold  
356 increase in T5 plants of the 397 line. However in some lines such as 320 BN2, 4  
357 and, 5 and 397 BN5, 6,110,120,127, and 198 XYN2 activity was silenced in T5  
358 plants and these lines were not studied further. As previously reported apoplastic  
359 XYN2 activity driven by the See1 promoter in T0 *Festuca* plants was not  
360 expressed until the early stages of leaf senescence and in the selected 397 and  
361 320 re-transformed lines XYN2 activity remained inducible on leaf senescence in  
362 T5 plants after repeated tillering (Figure 3).

363 In contrast to XYN2 activities, the levels of FAEA activity in T5 plants of the 320  
364 and 397 lines decreased an average 2.7 and 2.5 fold respectively compared with  
365 T0 plants (Figure 2a, b, e). This may be a result of variation in transgene  
366 expression in meristems during the formation of new tillers and/or biased selection  
367 of the more vigorous tillers during propagation.

368  
369 ***Effect of XYN2 and FAEA co- expression on growth and development of T5***  
370 ***plants.***

371 Measurements of growth and biomass of co-expressing T5 plants showed that at  
372 harvest both parameters were adversely affected by constitutive FAEA and  
373 senescence induced XYN2 expression. Co-expression of both FAEA and XYN2 in

374 the apoplast (line 320BN) resulted in T5 plants with narrower leaves and a 71 %  
375 decrease in mean biomass accumulation and a 31% decrease in mean plant  
376 height (Figure 4). The phenotype of plant 320 BN 3, compared to a non-  
377 transformed control plant at harvest is shown in Figure 4a. T5 plants co-  
378 expressing FAEA targeted to the vacuole, and XYN2 to the apoplast (397BN  
379 plants) were less affected and showed a 32% decrease in mean biomass levels  
380 and a 13 % decrease in mean leaf length compared to controls. Similar results  
381 were obtained previously in T5 plants with XYN2 constitutively expressed in the  
382 apoplast, but no effects on growth were found when XYN2 was expressed under a  
383 senescence promoter (Buanafina et al. 2012). FAEA targeted to the vacuole  
384 (Buanafina et al. 2008) or apoplast (Buanafina et al. 2010), at similar levels of  
385 expression, resulted in morphologically and developmentally normal T0 plants with  
386 little or no effect on fresh weight yield or plant height at harvest, contrary to the  
387 growth inhibition of constitutive FAEA expression in the T5 plants reported here.

388

389 **Effect of FAEA and XYN2 co-expression on cell wall composition of**  
390 **senescing leaves of T5 plants at harvest**

391 The effect of co-expressing FAEA and XYN2 on the levels of cell wall esterified  
392 hydroxycinnamic acids (HCAs), sugars and lignin was determined in leaves of  
393 selected T5 FAEA+XYN2 expressing plants and compared to clonal control non  
394 transformed plants.

395

396 **Cell wall phenolics:** Co-expression of constitutively expressed FAEA with  
397 senescence induced XYN2 both targeted to the apoplast (320 lines) had a small  
398 but not statistically significant effect on mean levels of cell wall *p*-coumaric acid

399 (Figure 5a), but resulted in highly significant reductions in the mean levels of  
400 esterified cell wall ferulate monomers (31%) (Figure 5a), and dimers (36%) (Figure  
401 5c), compared to control means. However when vacuolar targeted FAEA was  
402 combined with senescence induced apoplast targeted XYN2, (397 lines), this  
403 resulted in smaller non-significant reductions in the level of cell wall esterified  
404 ferulate monomers (4.6%) (Figure 5b), and dimers (2.6%) (Figure 5c).

405  
406 **Cell wall sugars:** Constitutive expression of FAEA and senescence  
407 induced apoplast expression of XYN2 also resulted in significant reductions in the  
408 mean levels of cell wall arabinose and xylose in both 397 and 320 lines compared  
409 with controls (Figure 5d). This reduction ranged from 10% for xylose and 19% for  
410 arabinose in 397 lines with vacuole targeted FAE to 18% for xylose and 34% for  
411 arabinose in 320 lines with apoplast targeted FAE compared to control plants  
412 (Figure 5d-e). As a consequence of these changes the arabinose:xylose ratio of  
413 the cell wall sugars decreased in both the 397 and 320 lines compared to control  
414 plants (Figure 5e).

415  
416 **Lignification:** Considering the potential of FAEA and XYN2 co-expression  
417 to release ferulates and diferulates as well as arabinose and xylose from the  
418 arabinoxylan backbone, and consequently to potentially decrease the cross-  
419 linking between arabinoxylan and lignin, the level of acetyl bromide soluble lignin  
420 was determined and compared to levels of total Klason lignin.  
421 No significant changes in Klason lignin levels of whole leaf biomass were found by  
422 co-expression of either apoplast or vacuole targeted FAEA with apoplast targeted  
423 xylanase (Figure 5f). However, the levels of acetyl bromide soluble lignin

424 extractable from partially purified cell walls (AIR) increased by 18% in plants co-  
425 expressing vacuole targeted FAEA with apoplast targeted xylanase (397 lines)  
426 and by 31% in plants co-expressing apoplast targeted FAEA and xylanase (320  
427 lines) (Figure 5f). Levels of ferulate monomers, dimers and total ferulates were  
428 negatively correlated ( $P=0.0028$ ,  $r^2= 0.755$ ;  $P=0.0008$   $r^2= 0.807$  and  $P= 0.0006$   $r^2=$   
429  $0.8197$ , respectively) to acetyl bromide lignin, but no significant correlation was  
430 found between *p*-coumaric acid and levels of acetyl bromide soluble lignin

431  
432 ***Effects of FAEA and XYN2 co-expression on cell wall digestion of senescing***  
433 ***leaves of selected T5 plants at harvest***

434 Three methods were used to assess the effects of FAEA and XYN2 co-expression  
435 on different aspects of post harvest cell wall biodegradability. The loss of cell wall  
436 esterified monomeric and dimeric ferulates and cell wall sugars on autodigestion  
437 of leaf samples was used to assess the effectiveness of *in-planta* expressed  
438 enzymes to degrade cell walls following cell disruption. Cellulase mediated sugar  
439 release from residual cell walls after autodigestion was used to determine the  
440 effects these changes had on subsequent sugar release, and *in vitro* dry matter  
441 digestibility (IVDMD) was used to determine the direct effect FAEA and XYN2 co-  
442 expression may have had on cell wall composition on the loss of biomass  
443 following direct treatment of whole tissues.

444 **Auto-digestion:** The effects of transgene-expressed FAEA and XYN2  
445 activities were determined by the release of cell wall esterified HCAs and sugars  
446 from senescing leaves using an auto-digestion procedure, which involved  
447 incubating macerated leaves in buffer for 48h and determining the released  
448 esterified ferulates diferulates and arabinoxylan sugars from the cell walls.

449 Significant amounts of the cell wall HCAs ( $p=0.05$ ) were removed on auto-  
450 digestion irrespective of whether FAE was expressed in the vacuole or apoplast.  
451 The released HCAs consisted of *p*-coumaric acid and both ferulate monomers and  
452 dimers, with mean losses of total HCAs for apoplast located FAE amounting to  
453 16%, and for vacuole located FAE, 9% of the total HCA content of the leaf cell  
454 walls compared with 3.6% for control plants (Figure 6a). ANOVA showed a  
455 significant contrast between control and the two transgenic lines for *p*CA ( $p=0.06$ ),  
456 and ferulate dimers ( $p=0.048$ ). The total amount of HCAs released on  
457 autodigestion was 6 to 10 times higher than previously found with plants  
458 expressing either vacuolar or apoplast FAEA, or apoplastic XYN2 alone, and 1.3  
459 and 2.4 times greater than where FAEA expressing tissues were digested in the  
460 presence of external applied XYN2, or where XYN2 expressing tissues were  
461 digested in the presence of external applied FAEA (Table 1).  
462 Auto-digestion also resulted in the release of significant amounts arabinose and  
463 xylose from cell walls of senescing leaves compared to controls (Figure 6b), with  
464 means losses of the total arabinoxylan content of the leaf cell walls amounting to  
465 16% for apoplast located FAE and 19% for vacuole located FAE compared with  
466 3% for control plants. In addition, the mean arabinose to xylose ratio decreased  
467 significantly in the cell wall residue following auto-digestion from 0.54 in control  
468 plants to 0.3 in the 397 lines and to 0.38 in the 320 plants. However the release of  
469 ferulate crosslinked arabinoxylan from co-expressing FAEA and XYN2 tissue on  
470 autodigestion could not be established.

474 release of glucose from autodigested cell walls treated with *T. ressei* cellulase.  
475 Plants of line 320, which showed reduced levels of ferulate monomers and dimers  
476 (Figure 5b&c) and the lowest levels of cell wall arabinoxylans (Figure 5d) showed  
477 a significant 31 % increase in the mean levels of glucose released from  
478 autodigested cell walls (Figure 6c). Plants from line 397 showed a 12 % increase  
479 in the mean levels of glucose released from autodigested cell walls treated with *T.*  
480 *ressei* cellulase (Figure 6c), and although this was not statistically significant,  
481 glucose released by two of the individual lines were significantly different from  
482 controls.

483 ***In vitro* dry matter digestibility (IVDMD).** The direct effect of reduced  
484 levels of cell wall HCAs and AX on tissue digestibility was also determined by the  
485 extent of biomass loss following the two-stage *in vitro* pepsin-cellulase solubility  
486 technique of Jones and Hayward (1975). Mean levels of IVDMD were not  
487 significantly different from controls in 397 plants and while mean levels of IVDMD  
488 increased by 5 percentage units in 320 plants this was not statistically significantly  
489 different from control values (Figure 6d).

490

## 491 **Discussion**

492 Following re-transformation of fescue plants constitutively expressing apoplast or  
493 vacuole targeted FAE, with a senescence induced apoplast targeted xylanase, a  
494 set of plants with both FAE and XYN2 enzyme activity, and with significantly  
495 reduced levels of esterified cell wall ferulates, diferulates and arabinoxylans was  
496 obtained. The expression of both constitutive and senescence induced FAE or  
497 XYN2 alone has been reported previously in forage grasses (Buanafina et al.

498 2004, 2006, 2010; 2012), but this is the first report of *in-planta* co-expression of  
499 both enzymes.  
500 FAE and XYN2 activities in co-expressing plants were initially found to be  
501 unstable on repeated tillering, with the level of xylanase activity increasing and  
502 FAE activity decreasing following five cycles of vegetative propagation. This could  
503 possibly be as a result of biased selection of the more vigorous tillers during  
504 propagation, as tillers were not screened for FAE activity, and some of the T5  
505 plants, which originally expressed both FAEA and XYN2 in T0 plants, were  
506 silenced for either FAE or xylanase expression. Increased levels of xylanase  
507 activity (Buanafina et al. 2012), and both increased and decreased GUS activity,  
508 as well as transgene silencing following tillering in tall fescue has been reported  
509 previously (Bettany et al. 1998) and re-emphasises the need for expression  
510 analysis when choosing tillers for vegetative plant propagation. As xylanase was  
511 not constitutively expressed in tillers but only at leaf senescence, any subsequent  
512 effects of xylanase expression on the plant phenotype would not have influenced  
513 the visual selection of tillers at the time of propagation. It is therefore possible that  
514 any deleterious effects of constitutive FAE activity on plant development could  
515 have been selected against by this procedure. Constitutive apoplastic expression  
516 of FAE in *Festuca* was previously found to have little effect on the growth and  
517 development of T0 plants (Buanafina et al. 2010), but on repeated vegetative  
518 propagation by tillering these plants developed a new and stable phenotype with  
519 narrow leaves and with modified leaf growth kinetics. The FAE and xylanase co-  
520 expressing plants reported in this work also developed this narrow leaf phenotype  
521 following repeated tillering, and is suspected to be responsible for the reduction in

522 biomass. To overcome this in the future it may be advisable to target both  
523 xylanase and FAE expression to the apoplast under senescence promoters.  
524 The initial instability of FAE and XYN2 activities in co-expressing plants on  
525 repeated tillering might indicate that transgene expression is unpredictably  
526 modified during the formation of new meristems from somatic stem cells. This may  
527 suggest evidence for the mitotic modification of epigenetic effects similar to the  
528 transcriptional silencing of transgene expression in plants, associated with  
529 meiotically heritable epigenetic modifications (Matzke and Matzke, 1988). A similar  
530 effect was reported with lateral buds in plants regenerated from cultured leaf discs,  
531 which showed that “once established, competence for silencing can persist in  
532 dormant, actively growing and de-novo established shoot meristems” (Kunz et al.  
533 1996).  
534 In contrast to previous reports where high levels of apoplast located XYN2 activity  
535 was found to induce pathogen defence responses (Buanafina et al. 2012), plants  
536 expressing similar levels of XYN2 activity, but with low FAEA activities, showed no  
537 signs of xylanase induced pathogen responses, such as high levels of cell wall  
538 ferulate dimers or necrotic lesions on the leaves. Comparing the mean levels of  
539 HCAs and AX of cell walls of senescing leaves of co-expressing plants with the  
540 original parent plants expressing apoplast FAE only, and with plants expressing  
541 senescence induced xylanase only, it is possible to conclude that constitutive  
542 expression of FAE in the apoplast may have been sufficient to overcome the  
543 ferulate dimerisation triggered by apoplast located xylanase (Figure 7). Possible  
544 reasons for this may be that either there is a continual cycling of dimers with FAE  
545 removing them faster than they can be added by the action of xylanase induction  
546 of ethylene and H<sub>2</sub>O<sub>2</sub>, or that constitutive FAE expression in the apoplast results in

547 a reduction in the ferulate levels such that even with an increase in cell wall  
548 esterified diferulates due to xylanase induction of crosslinking via ethylene  
549 induced H<sub>2</sub>O<sub>2</sub> production in the cell wall, the levels of diferulates remain below  
550 control levels.

551 The finding that co-expression of FAEA and XYN2 significantly increased the  
552 amount of acetyl bromide soluble lignin, with a significant negative correlation  
553 between ferulates and acetyl lignin levels suggests that the ester linkages in some  
554 ferulate dimers may be reduced by expressed FAEA, resulting in an increase in  
555 acetyl bromide lignin solubility. Furthermore, with reduced levels of ferulate  
556 monomers the rate of ferulate dimerisation may be reduced and consequently the  
557 level of ether linkages to lignin. Similar increases in lignin solubility were also  
558 found in alfalfa expressing vacuole or apoplast FAE, but with increased residual  
559 lignin content following digestion (Badhan et al. 2014).

560 The limited effects of co-expression of FAEA and XYN on IVDMD and cellulase  
561 mediated sugar release of the 397 plants may be partially due to the much lower  
562 mean levels of vacuolar FAE activity of T5 plants (75 units g fresh wt<sup>-1</sup>) than the  
563 mean levels of vacuolar FAE activity previously reported (200-300 units g fresh wt  
564<sup>-1</sup>) in T0 plants which showed increases in IVDMD of 6 to 10 percentage units  
565 (Buanafina et al. 2008). In addition much higher levels of apoplastic xylanase  
566 activities (7500 mU g fresh wt<sup>-1</sup>) were found in these co-expressing T5 plants  
567 than in T0 plants expressing only senescence induced apoplastic xylanase (400  
568 mU g fresh wt<sup>-1</sup>). These lower activities previously resulted in both a 12  
569 percentage units decrease in IVDMD and a 30% decrease in cellulase mediated  
570 sugar release due to induced pathogen defense responses resulting in enhanced  
571 ferulate dimerization (Buanafina et al. 2012).

572 It is difficult therefore to reconcile the observed changes in cell wall structure and  
573 enhanced post harvest deferuloylation of cell wall arabinoxylans in plants  
574 expressing both FAE and xylanase with the reduced levels of cellulase-mediated  
575 digestion. However, this may be partially explained by recent studies showing that  
576 arabinoxylan adsorption onto cellulose is controlled by the fine structure of the  
577 arabinoxylan. In particular where a reduction in the arabinose content of  
578 arabinoxylan leads to stronger adhesion between xylan and cellulose (Köhnke et  
579 al. 2011) and where a lower cell wall arabinose:xylose ratio lead to reduced  
580 enzymatic digestibility of *Miscanthus* lignocellulose (Li et al. 2013).

581 In contrast to first and second generation biofuels we anticipate that future third  
582 generation biofuels may well be produced by combined saccharification and  
583 fermentation of lignocellulose biomass under mild processing conditions In this  
584 respect expressing cell wall degrading enzymes such as xylanases (Bae et al.  
585 2006; Shen et al. 2012; Borkhardt et al. 2010; Kim et al. 2011; Chou et al. 2011) ,  
586 cellulases (Klose et al. 2013; Kawazu et al. 1999; Ransom et al. 2007; Oraby et al.  
587 2007; Hood et al. 2007; Klose et al. 2012), esterases (Harholt et al. 2010;  
588 Buanafina et al. 2006, 2008, 2010) and glycosidases (Montalvo-Rodriguez et al.  
589 2000) have been shown to improve post harvest cell wall degradation and provide  
590 examples of how progress is being made towards generating novel biomass for  
591 these third generation biofuels.

## 593 **Conclusions**

594 The present study demonstrates the principle that the synergic effect of xylanase  
595 on FAE mediated release of ferulates from cell wall arabinoxylans can be  
596 achieved by *in-planta* co-expression of these two cell well degrading enzymes.

597 Targeted co-expression of a fungal FAE and xylanase to the apoplast was shown  
598 to significantly reduced the levels of esterified ferulates, diferulates and  
599 arabinoxylans of the cell wall and increase the extent of post-harvest cell wall  
600 deconstruction of the relatively low digestible temperate forage grass *Festuca*  
601 *arundinacea*. Higher levels of HCAs and arabinoxylan were removed from the cell  
602 wall following autodigestion, and significantly increased cellulase mediated sugar  
603 release and lignin solubility were found compared to plants expressing FAE or  
604 xylanase alone. It is clear that for future application the effect of constitutive FAE  
605 expression in the apoplast on biomass yield needs to be mitigated, perhaps by  
606 senescence induced apoplast expression of both FAE and xylanase. We consider  
607 that this technology may have potential to contribute to more efficient and  
608 environmentally benign third generation biofuel production, characterized by mild  
609 enzyme based post-harvest treatment of genetically modified lignocellulose  
610 biomass in a combined saccharification and fermentation system.

837 **Figure 1. Molecular aspects.**

838 **(a)** Vector components and **(b)** vector combinations used for re-transformation of  
839 plants expressing an *Aspergillus niger* gene (*faeA*) targeted to the vacuole  
840 (pINH1 $\Delta$ ) or apoplast (pIGB6), under the rice actin promoter with a *Trichoderma*  
841 *reesei*  $\beta$ -1,4 endo-xylanase gene (*xyn2*) targeted to the apoplast under a  
842 senescence promoter (LmSee1) (pIOM6) See1 is a *Lolium multiflorum*  
843 senescence enhanced gene promoter and intron. Aleurain is a barley aleurain  
844 signal sequence with a vacuolar targeting motif. PPI is a potato protease inhibitor  
845 conferring apoplast targeting. **(c)** Southern blot analysis of digested genomic DNA  
846 hybridised with *faeA* probe (a) or with *xyn2* probe (b). C+1, C+1\* and C1+1# =  
847 control plant DNA with one genome equivalent of plasmids pINH1 $\Delta$ ; or pIGB6 or  
848 pIOM6 respectively. DNA digested with HindIII which excises a 1.2-Kb *faeA*  
849 fragment (a), or EcoR1/NotI, which cuts out a 0.595 Kb *xyn2* fragment (b). Each  
850 lane contains 10  $\mu$ g DNA. The expected fragments [1.2 Kb in (a) and 595 bp in  
851 (b)] for intact transgenes are indicated by arrow. Sizes of molecular weight  
852 markers on the left.

853

854 **Figure 2. FAEA and xylanase activities of leaf extracts of senescing T0 and**  
855 **T5 plants.**

856 **(a)** Levels of FAEA enzyme activity with ethyl ferulate in T0 plants of line 320Bn  
857 **(b)** Levels of FAEA enzyme activities in T0 plants of line 397Bn Activities are  
858 compared with the FAE activities in the parent FAE expressing plants. **(c)** Levels  
859 of XYN2 enzyme activities with Oat Azo-xylan in T0 plants of line 320BN. **(d)**

860 Levels of XYN2 enzyme activities in T0 plants of line 397BN . **(e)** Levels of FAEA  
861 enzyme activity with ethyl ferulate in T5 plants of lines 320BN and 397BN. **(f)**  
862 Levels of XYN2 enzyme activities in T5 plants of lines 320BN and 397BN. T5  
863 plants had undergone 5 cycles of vegetative propagation by *in vivo* tillering. Plants  
864 were constitutively expressing vacuole (Line 397) or apoplast (Line 320) targeted  
865 FAEA, and senescence induced apoplast targeted XYN2. Control plants were non  
866 transformed regenerates of the same *Festuca* genotype. Single determinations  
867 from independently transformed or control plants. \* indicates plants which were  
868 subsequently characterized in detail. One unit of FAE activity equals 1 µg ferulic  
869 acid released from ethyl ferulate in 24 h at 28°C. One unit of xylanase activity  
870 equals 1 µmole xylose released from Azoxylan / min at 37 °C.

871

872 **Figure 3.** Senescence induced xylanase activity in leaves of two T5 plants, 320  
873 BN5 and 320 BN3 with FAE under a constitutive promoter and senescence  
874 induced xylanase, both targeted to the apoplast after repeated vegetative  
875 propagation by *in vivo* tillering. Single determinations from pooled leaves of  
876 individual plants

877

878 **Figure 4. Effects on plant growth.**

879 **(a)** Control *Festuca* plant (a) and a T5 plant 320 BN3 (b) at harvest. Plant 320 BN3  
880 was constitutively expressing FAEA and senescence induced apoplast targeted  
881 XYN2. **(b)** Effect of FAEA and XYN2 expression on leaf growth and **(c)** biomass  
882 accumulation of T5 plants at harvest. Plants were constitutively expressing  
883 vacuole (Line 397) or apoplast (Line 320) targeted FAEA, and senescence  
884 induced apoplast targeted XYN2. Plants harvested after 8-10 months when the

910 cell walls (A, B). Mean  $\pm$  SEM of triplicate (C) or single (D) determinations from (n)  
911 independently transformed or control plants. Based on in-house QC material RSD  
912 and %CV were STM 0.26 RSD = 0.1904 %CV= 1.904 for IVDMD.

913

914 **Figure 7.** Comparison of the mean levels of HCAs (a) and AX (b) of cell walls of  
915 senescing leaves of T5 plants constitutively expressing FAE and xylanase  
916 targeted to the apoplast with the original parent plant expressing apoplast FAE  
917 only (T27), and with plants expressing senescence induced xylanase only (X1-  
918 X9). Mean  $\pm$  SEM (n=3) determination from n plants. Corresponding control plants  
919 for each vector =100%. For further details on the characteristics of the parent plant  
920 266Bn10 see plant T27 in Buanafina et al 2010 and for plants X1-X9 see  
921 Buanafina et al. (2012).

922

923

924 **Table 1**

925 Levels of total HCAs released from leaf cell walls of transformed plants on  
 926 autodigestion. Values were corrected for the soluble HCAs release from  
 927 corresponding control plants, which varied from  $20.0 \pm 7.3$  (n=11) to  $34.4 \pm 7.1$   
 928 (n=11)  $\mu\text{g/g}$  fresh wt. in the absence or presence of applied xylanase or FAE  
 929 respectively. (\* based on 80% water content of leaves)

930

Plant	- Xylanase	+ Xylanase (1000U)	+FAE (1U)	Reference
Constitutive vacuole FAE	$27 \pm 9$ (n= 12)	$152 \pm 23$ (n=12)	-	Buanafina et al. 2008
Constitutive apoplast FAE	$21 \pm 2$ (n= 10)	$155 \pm 25$ (n= 10)	-	Buanafina et al. 2010
Constitutive golgi FAE	$26 \pm 2$ (n= 5)	$135 \pm 20$ (n= 5)	-	Buanafina et al. 2010
Constitutive ER FAE	$22 \pm 2$ (n= 6)	$140 \pm 35$ (n= 6)	-	Buanafina et al. 2010
Senescence apoplast xylanase	$30 \pm 10$ (n= 3)	-	$72 \pm 50$ (n= 3)	Buanafina et al. 2012
* Constitutive apoplast FAE + senescence apoplast xylanase	$297 \pm 46$ (n= 2)	-	-	This paper Fig 5
* Constitutive vacuole FAE + senescence vacuole xylanase	$213 \pm 52$ (n= 4)	-	-	This paper Fig 5
