HIV prevalence and Armed Conflict Dataset (v.2)

March 2011

SUMMARY:

This dataset was constructed by merging the UCDP/PRIO Armed Conflict dataset (v.4-2010)\(^1\) and data from UNAIDS which was prepared for the 2010 Report on the Global AIDS Epidemic, which details HIV prevalence between 1990-2009.\(^2\)

Where the HIV prevalence of a country is shaded in yellow, the occurrence of conflict is indicated in the respective year.

It is intended to give a straightforward and immediate impression of HIV prevalence rates during/after conflict, thus providing scope for further research and debate on the relationship between HIV and conflict.

DEFINITIONS:

Armed conflict

UCDP defines armed conflict as ‘a contested incompatibility that concerns government and/or territory where the use of armed force between two parties, of which at least one is the government of a state, results in at least 25 battle-related deaths in one calendar year.’\(^3\)

HIV Prevalence

In this dataset HIV prevalence refers to Adults aged 15-49 as a percentage of a given country’s population. Prevalence rates for regions are also given.\(^4\)

---

\(^2\) HIV estimates with uncertainty bounds 1990-2009’ (1.3MB, xls)

\(^3\) Definition of ‘Armed Conflict’.

\(^4\) HIV estimates with uncertainty bounds 2001, 2009.’ (163KB, xls)
Notes:

1. In some cases prevalence rates were not given by the UNAIDS report. These have been left blank. In other cases only high and/or low estimates were given, where this has happened the range of values is stated beside the country name.

2. The country names and regions are taken from the UNAIDS Report NOT from the UCDP/PRIO dataset. Where prevalence data was not given in the 2010 UNAIDS report yet the country was listed in the 2008 report, ‘not listed’ is stated beside the country in question. Prevalence is also left blank.

3. The temporal aspect of a conflict is not addressed in the definition: “The calendar year is the basic unit of every observation. Thus, if a conflict during the period June–September results in 30 casualties, that year will be recorded as a year of conflict. However, if the same number of casualties occurred in the period November–February and the conflict failed to reach the threshold of 25 battle-related deaths in either calendar year, neither year will be coded as in conflict. This has a number of consequences that will be discussed below. Start dates frequently refer to years prior to the first calendar year of a conflict, as the start of a conflict might be in a year with less than 25 casualties. Small conflicts might not be included. Certain observations might be based on a single event, such as the Omagh bombing in Northern Ireland in 1998, which exceeded the minimum threshold for armed conflict.”

Likewise, the conflict is considered to be terminated when the threshold of 25 battle related deaths is not reached in any calendar year.

4. Occasionally more than one conflict has taken place in a single country in a given year. Whilst recorded in the UCDP dataset, this is NOT recorded or indicated in the HIV-Conflict dataset. Nor is the intensity of the conflict recorded (i.e. War or Minor Conflict), or the type of conflict (domestic/international). We only indicate that a conflict has taken place in a given year.

5. All data on HIV prevalence has been taken from the 2010 Report. This will be updated when the 2012 report becomes available. This is because although updated estimates will be made available for the regions before this time (e.g. AIDS epidemic updates), this data does not list individual countries. As methods of data collection and statistical modelling change from year to year, it is not possible to combine reports as estimates are re-done. Furthermore the data set is also problematic, as data collection techniques have improved over time, therefore even redoing estimations using new modelling techniques may not give a perfectly accurate estimate of prevalence in earlier years. Nonetheless, the data which is in use from the 2010 report represents the most up to date and fullest dataset on HIV prevalence currently available which allows an assessment of trends over time. For further information on the methodology whereby the 2010 estimates were produced, see “Methodology-Understanding the latest estimates”.
